- **ANNEX & Overview about Pilot Projects**

Solar radiation & heat production

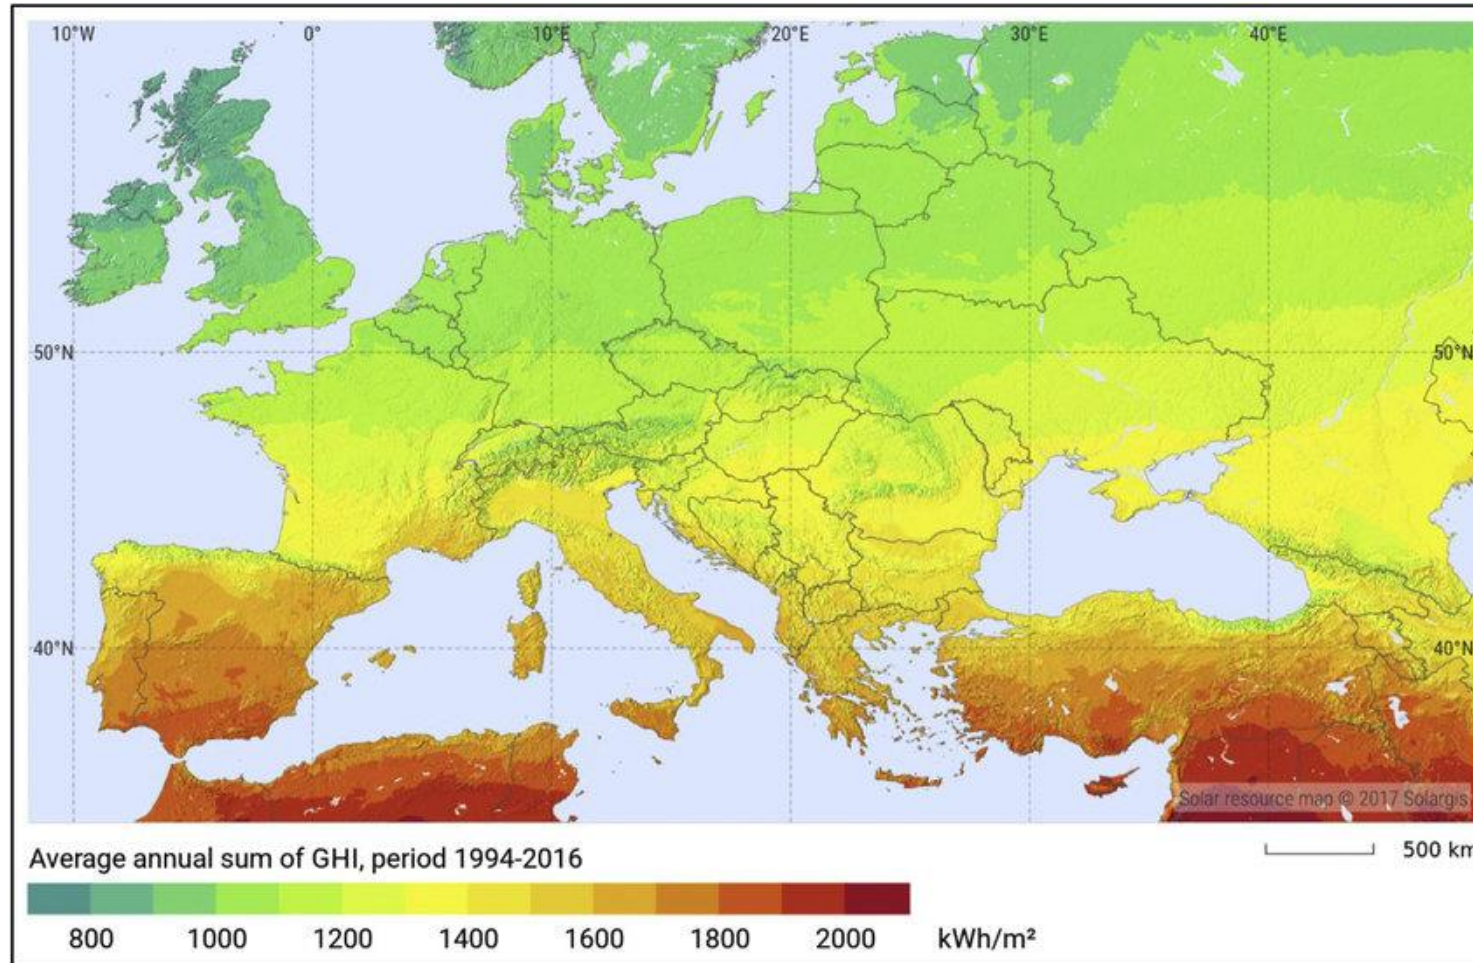

- **approximate solar radiation in Central Europe at midday:** $\pm 1000 \text{ watts / m}^2$
(under perfect weather conditions)
- **annual average of solar radiation in Central Europe:** $\pm 125 \text{ W/ m}^2$
(about $1/8$ of perfect conditions)
- **approx. average solar radiation on collector:**
 $1/8 \times 24\text{h}$ (3h per day)
 or $1/8 \times 8760 \text{ h/a} = \pm 1100 \text{ operating hours /a}$
 $\rightarrow \pm \underline{1100 \text{ kW/h per m}^2\text{a}}$

Source: pixabay

Solar radiation & heat production

- Annual yield depends on many factors
 - weather
 - collector type
 - site specifications
 - plant dimensioning and energy utilization
 - installation angle
 - etc...

Source: Gholami & Røstvik. 2020 [2]

Overview - Solar thermal systems & operating modes

- **Where to place solar heat collectors?**

- Ground mounted solar collectors

(cheapest solution; depending on land prices, distance to the existing pipe system or consumer, general heat utilization, storage & many other parameters)

- Roof mounted solar collectors (interesting for large and flat rooftop areas)

- **Most common collector types on the market?**

- Flat plate collectors
- Evacuated tube collectors

Overview - Solar thermal systems & operating modes

types	flat plate collectors	evacuated tube collectors		
	conventional / high performance collectors	indirect flow	direct flow	
		heat-pipe principle	evacuated tube	Compound Parabolic Concentrator
		 Source: baunetz_wissen		

Source: AGFW & baunetz_wissen ; adjusted by AGFW-Project GmbH [5]

General principle of flat plate collectors

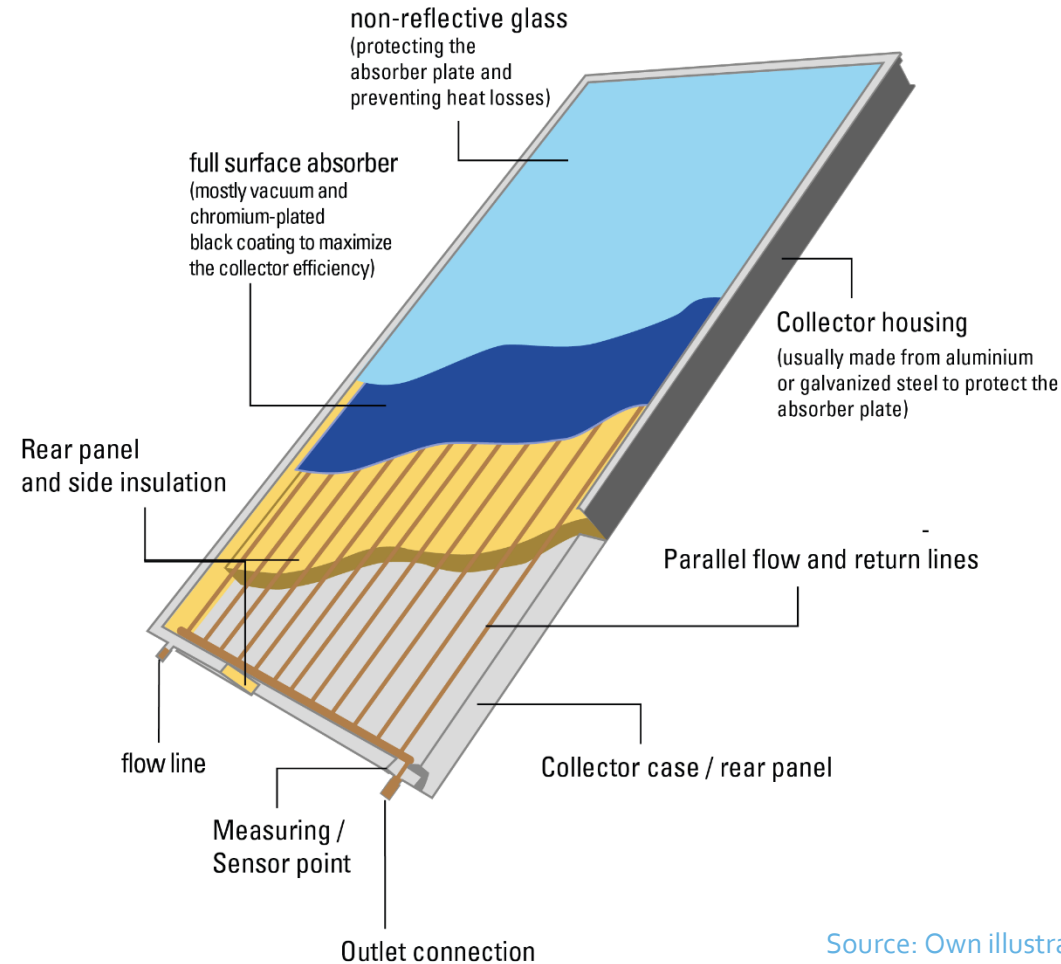

- Flat plate collectors are using a flat absorber plate that is isolated with mineral wool, polyurethane foam or other materials
- This isolation is less efficient than the vacuum isolation of evacuated tube collectors
- High performance flat plate collectors are operating with copper absorbers

Source & copyright: Stefan Simonides

General principle of flat plate collectors

- approx. production of 500-550 kWh annual yield per gross collector surface
- Reach operating temperatures from 30 to 80 °C
- If well planned, can reach stagnation temperatures from 150-200 °C
- Can be installed in series or parallel connection
- Installation angle variable
- FPCs usually work with a medium from water and antifreeze fluid

Source: Own illustrations AGFW-Projekt GmbH

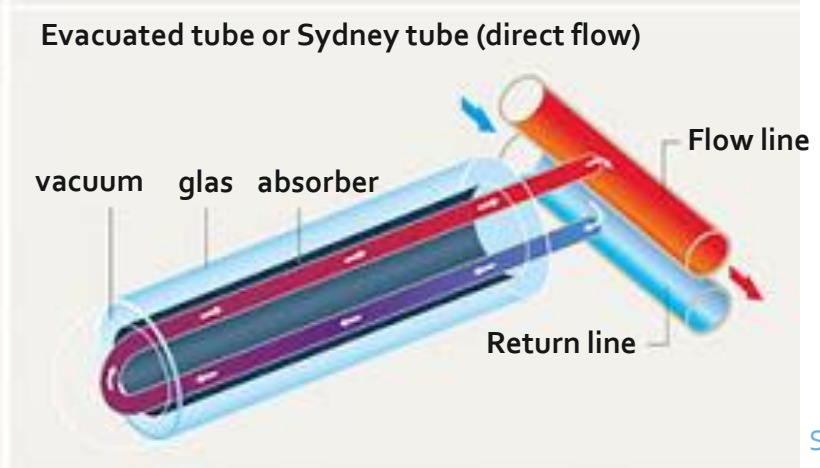

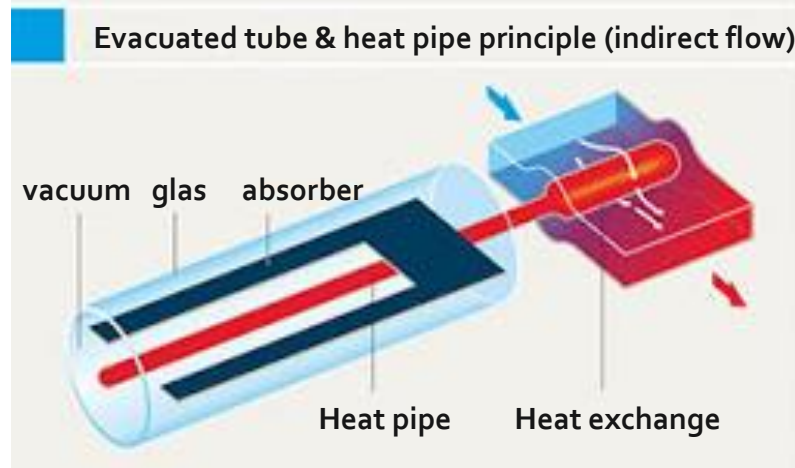

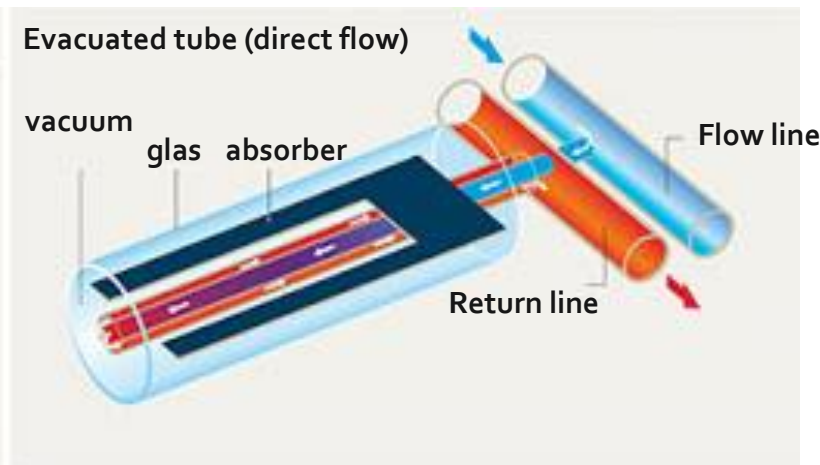

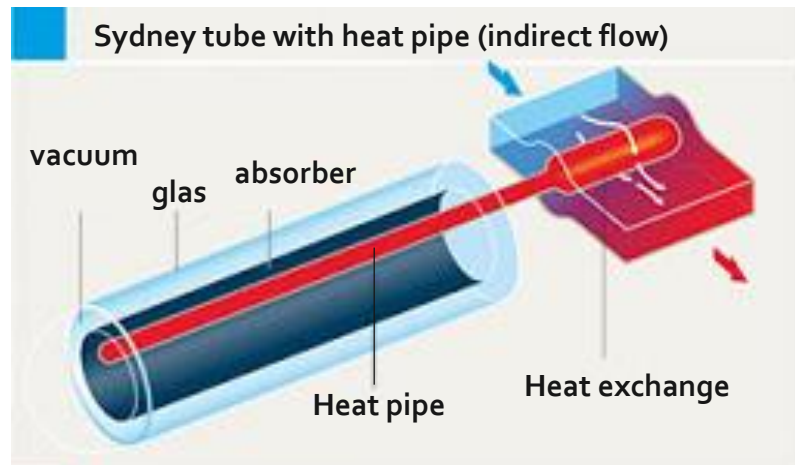

General principle of evacuated tube collectors

- Evacuated tube collectors are typically designed with parallel rows of double-hulled glass tubes
- The very high thermal insulation can be reached by the vacuum in the outer tube
- Heat pipes are transmitting the heat to the heat medium (indirect flow) or direct flow lines transport the heat medium in an „U-shape“ through the inner glass tube
- Higher temperature levels can be achieved (above 200 °C up to 350°C)
- higher heat extraction efficiency compared with FPCs in the temperature range above 80°C
- Efficiency levels are also higher than flat plate collectors
- Higher investment costs than flat plate collectors

Source: Ritter-XL-Solar [6]

General principle of evacuated tube collectors

Source: Solarwärme (2014); translated & adjusted [7]

Indirect-flow evacuated tube collectors or heat-pipe principle

- Heat transfer tube is installed on the backside of an absorber panel
- The tube is filled with a heat medium (mostly water or alcohol under negative pressure)
- The heat transfer takes place at the top of the tube

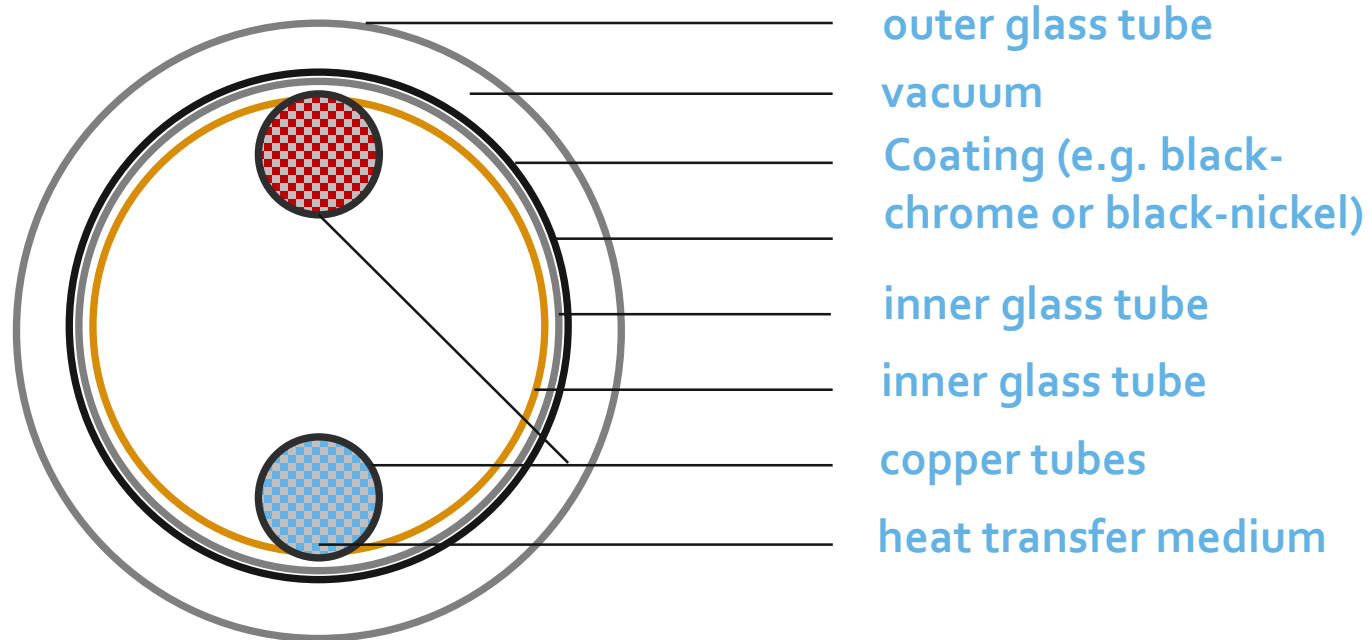

(condensation of heat medium → released heat is transferred to the collector pipe system

→ condensate of heat medium returns to the bottom of the glass tube and heats up again)

→ Works also at days with low solar radiation, because condensate evaporates already at low temperatures of about 25 °C (collector temperature)

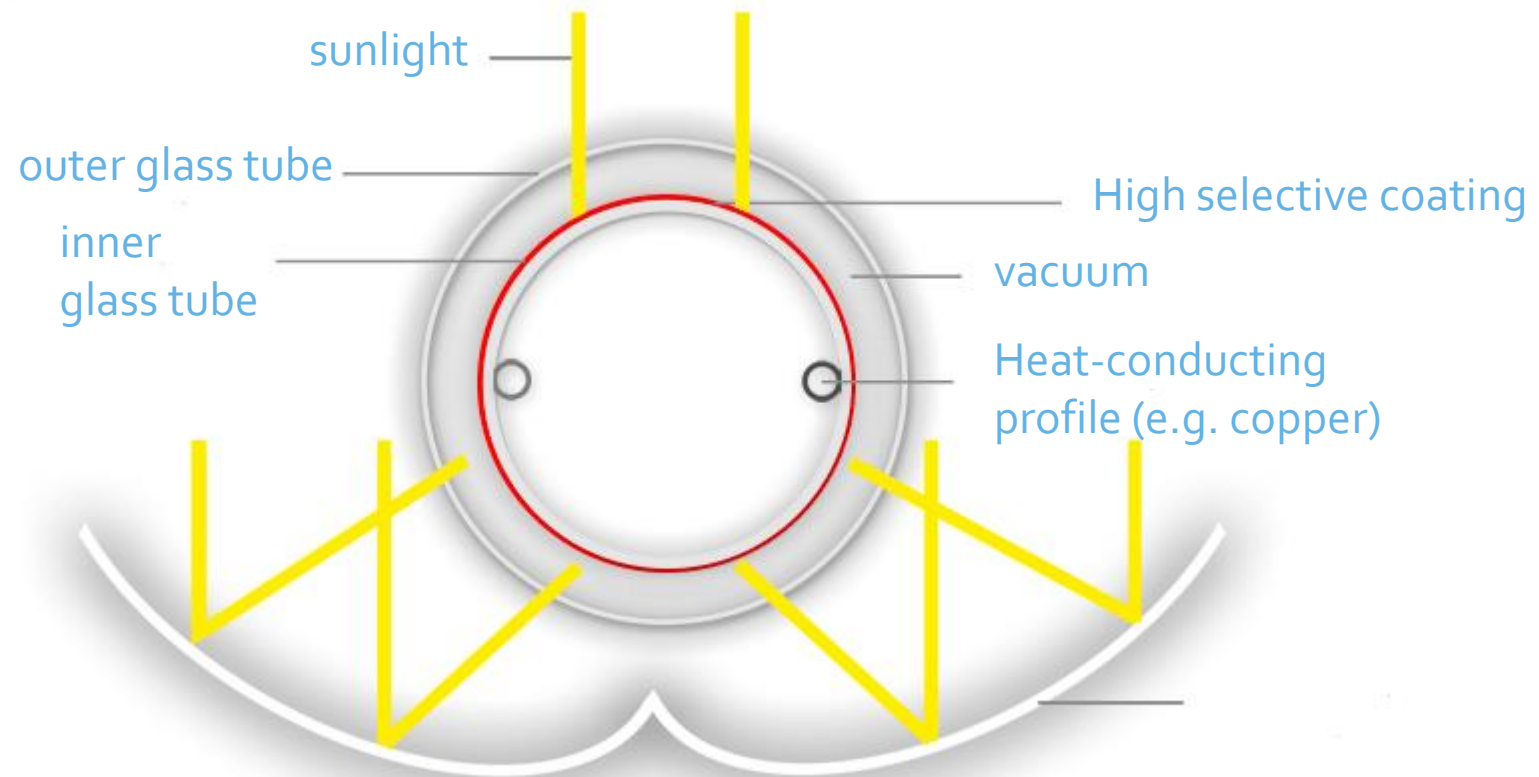

→ Less pressure loss due to direct heat exchange at the flow line

Evacuated tube collectors

Compound Parabolic Concentrator (CPCs)

- Capability of **reflecting** to the absorber **all** of the incident radiation within **wide limits**
 - changing solar orientation can be **reduced** by using a trough with two sections of a parabola facing each other
 - By using **multiple internal reflections**, any radiation entering the aperture within the collector acceptance angle finds its way to the absorber surface
- High investment costs

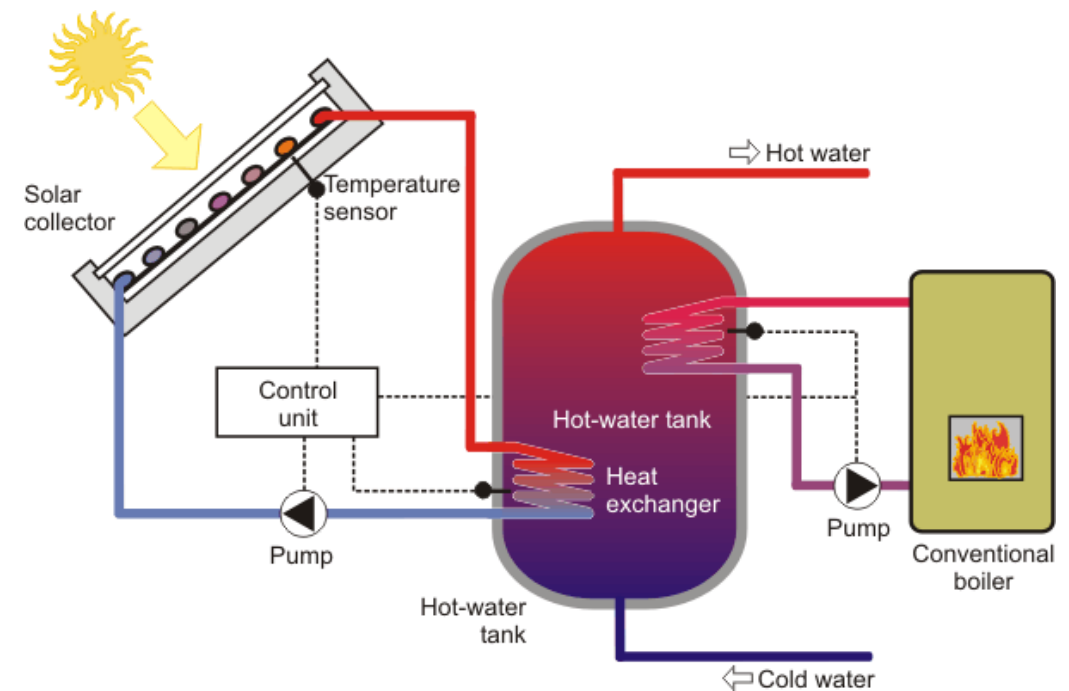

Source: Frank Tebbe [8]

Characteristics of the heat medium

- SDH-Heat medium \neq district heating water
- Heat is exchanged at the heating station / storage tank via heat exchangers
- Heat is exchanged at the top of evacuated tube-collectors operating with indirect flow

Important characteristics for SDH heat medium:

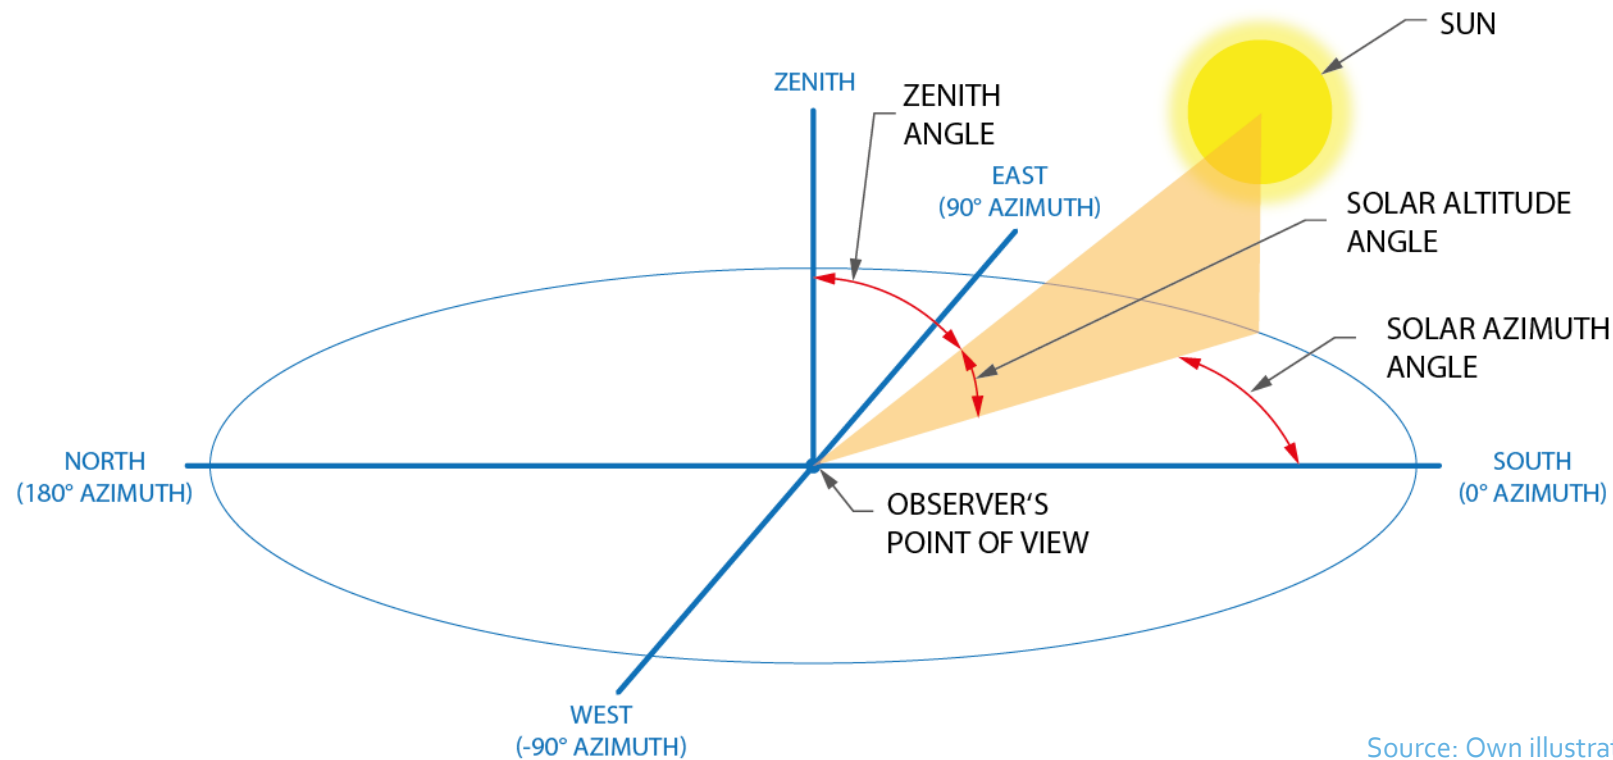

- High temperature stability
- Low viscosity (due to heat capacity)
- High heat capacity
- Environmental compatibility
- Corrosion protection (demineralised water etc.)
- Frost protection (usually mixture of water and alcohol used; e.g Propylene Glycol)

Source: Volker Quaschnig [9]

Installation & planning requirements

Collector orientation / tilt (set-up angle) & efficiency

Source: Own illustrations AGFW-Project GmbH

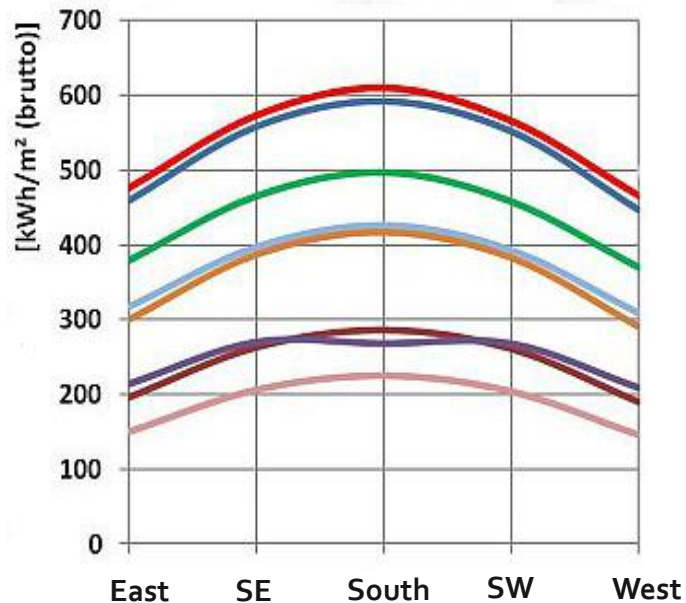

Installation & planning requirements

Collector orientation / tilt & efficiency

- absorber gets the most efficient energy when collector axis is absolute vertical to the sun rays
 - change related to hour and season
 - hence the collectors must be oriented in the latitude right angle and slope
 - For Europe usually 25° to 45° is the most ideal “solar altitude angle” to mount, but also angles up to 60° e.g. on rooftops can be found
 - The higher the tilt the higher the collector yield during winter times / days with low solar radiation
 - high tilts minimize peaks and thermal stagnation in summer, but also the temperature level
- **Orientation generally always depends on the site specific operation / planned heat utilization (space heating / domestic hot water preparation / both / with or without seasonal storage) / heat demand etc.**

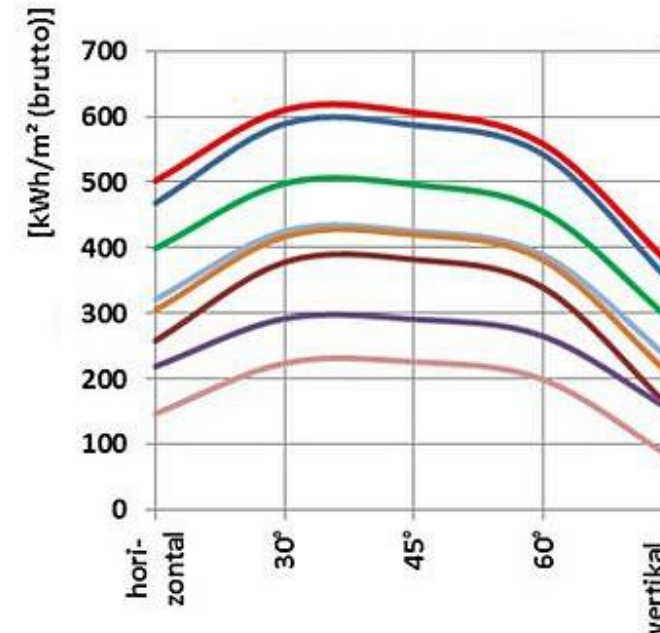

Installation & planning requirements

Collector orientation / set-up angle & efficiency

Calculative EXAMPLE for different varieties of solar thermal collectors.

- Location: Würzburg, Germany
- Set-up angle: 75° orientation: varying
- Average collector temp.: 75 C°

Calculative EXAMPLE for different varieties of solar thermal collectors.

- Location: Würzburg, Germany
- Orientation: South; tilt: varying
- Average collector temp.: 75 C°

Source of example: Paradigma (translated and adjusted) [10]

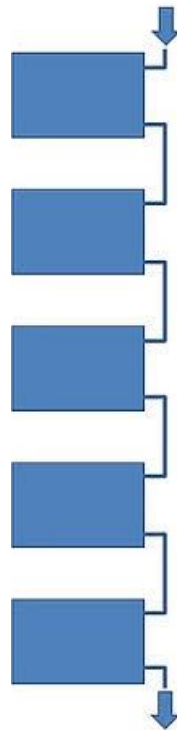

Installation & planning requirements

Collector arrangement & circuitry

- large scale solar-thermal plants can be designed in series and/or parallel connections

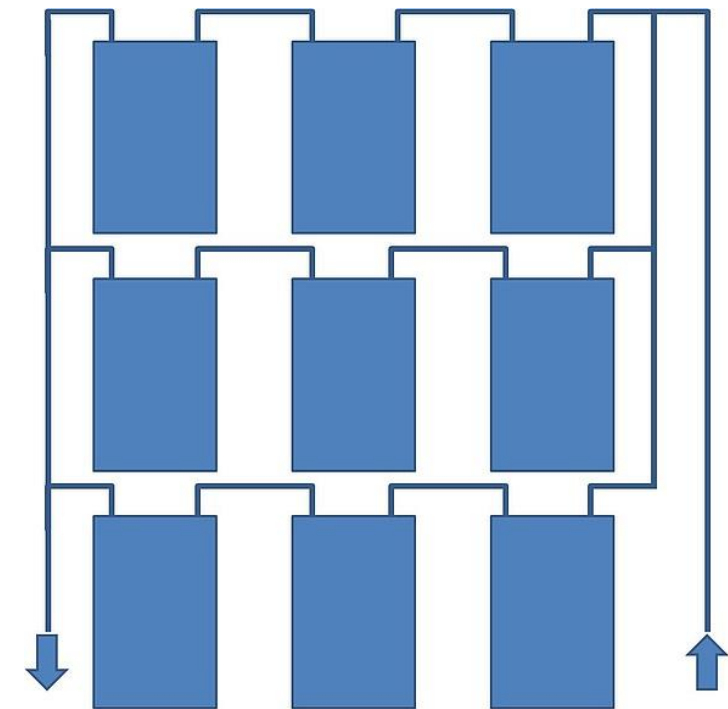

Series connection

- high pressure losses
- high pump capacity
- even flow rates
- High
- Less piping installation / lower investment costs

Parallel connection

- low pressure losses
- less pump capacity
- Tichelmann principle** necessary for even flow rates
- Lower flow rates
- ΔT depends on collectors in series connection
- for large scale SDH-plants

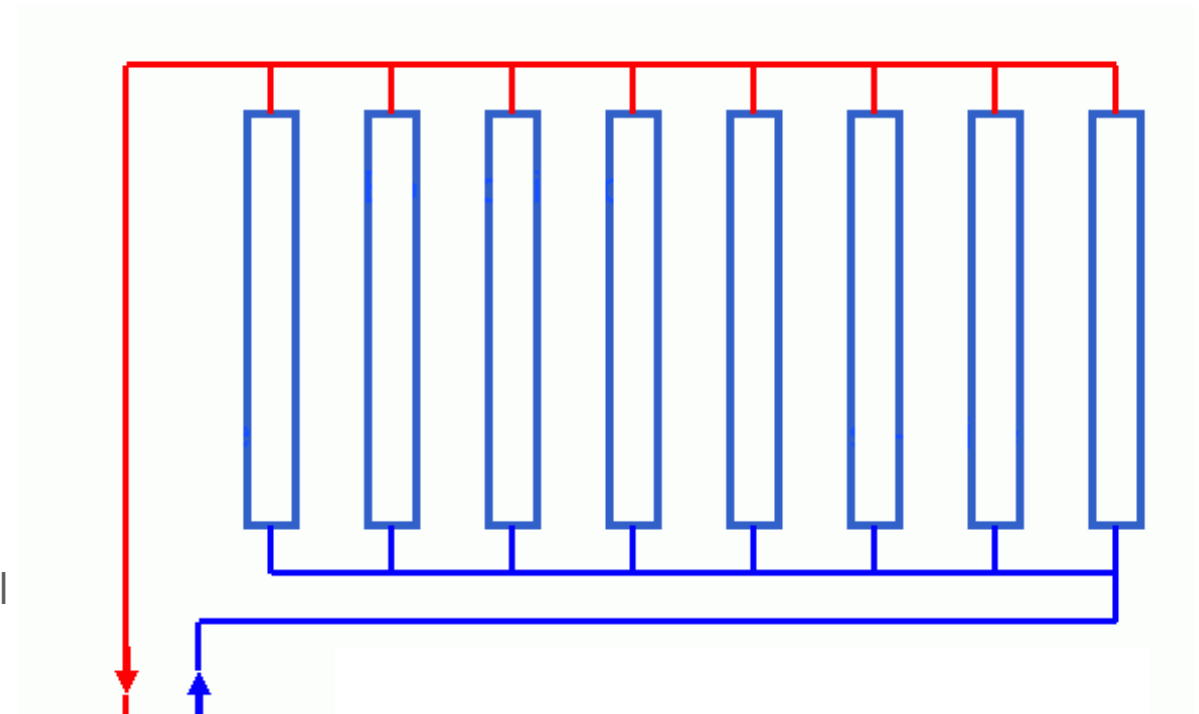

Series & parallel connection. Own illustrations AGFW-Project GmbH

Installation & planning requirements

„Tichelmann-principle“:

- equal length ratio between flow line & return line
 - Heat medium always covers same distance
 - Equal pressure losses within the system
 - Equal mass flux distribution
- Higher piping needed
- Fewer regulation effort needed e.g. through control valves

Tichelmann-principle. Own illustrations AGFW-Projekt GmbH

Stagnation handling

Design Temperature

Design temperature is the maximum temperature a solar thermal collector or collector loop part can stand without being damaged. The design temperature of the entire solar loop is determined by the collector loop component with the lowest design temperature.

Operation temperature

Operation temperature is defined as the maximum temperature of a solar thermal collector or the collector loop where “normal” operation shall be pursued.

- determined by maximum storage temperature
- determined by heat demand of the connected DH-system

Stagnation

Stagnation describes the state of a solar thermal system in which (by any reason) the flow in the collector loop is interrupted although sufficient solar irradiance is available for operation of the collector loop.

- the fluid in the solar thermal collector is heated up to a temperature where the absorbed energy equals the losses

(Source: Frank, E., Mauthner, F., & Fischer, S. (2015). [11])

Stagnation handling

„Stagnation handling...

...if stagnation is an accepted operation mode!“

„Overheating prevention...

... If stagnation is not an accepted operation mode!“

Constructional precautions, security concept with regard to plant-dimensioning have to be THE important aspects in the planing phase!

(Quoted from Frank, E., Mauthner, F., & Fischer, S. (2015). [11])

Keymark-Certificates: <http://www.estif.org/solarkeymarknew/>

Summary of EN 12975 Test Results, annex to Solar KEYMARK Certificate		Licence Number	
		Issued	2015-11-30

Stagnation temperature - Weather conditions see note 2	Tstg	301	°C
Effective thermal capacity	ceff = C/Ag	9.18	kJ/(m²K)
Max. intende operation temperature - see note 3	Tmax,op	160	°C
Max. operation pressure - see note 3	pmax,op	1000	kPa

(Example of a keymark-certificate. Source: www.estif.org)

Stagnation handling

Effects of stagnation:

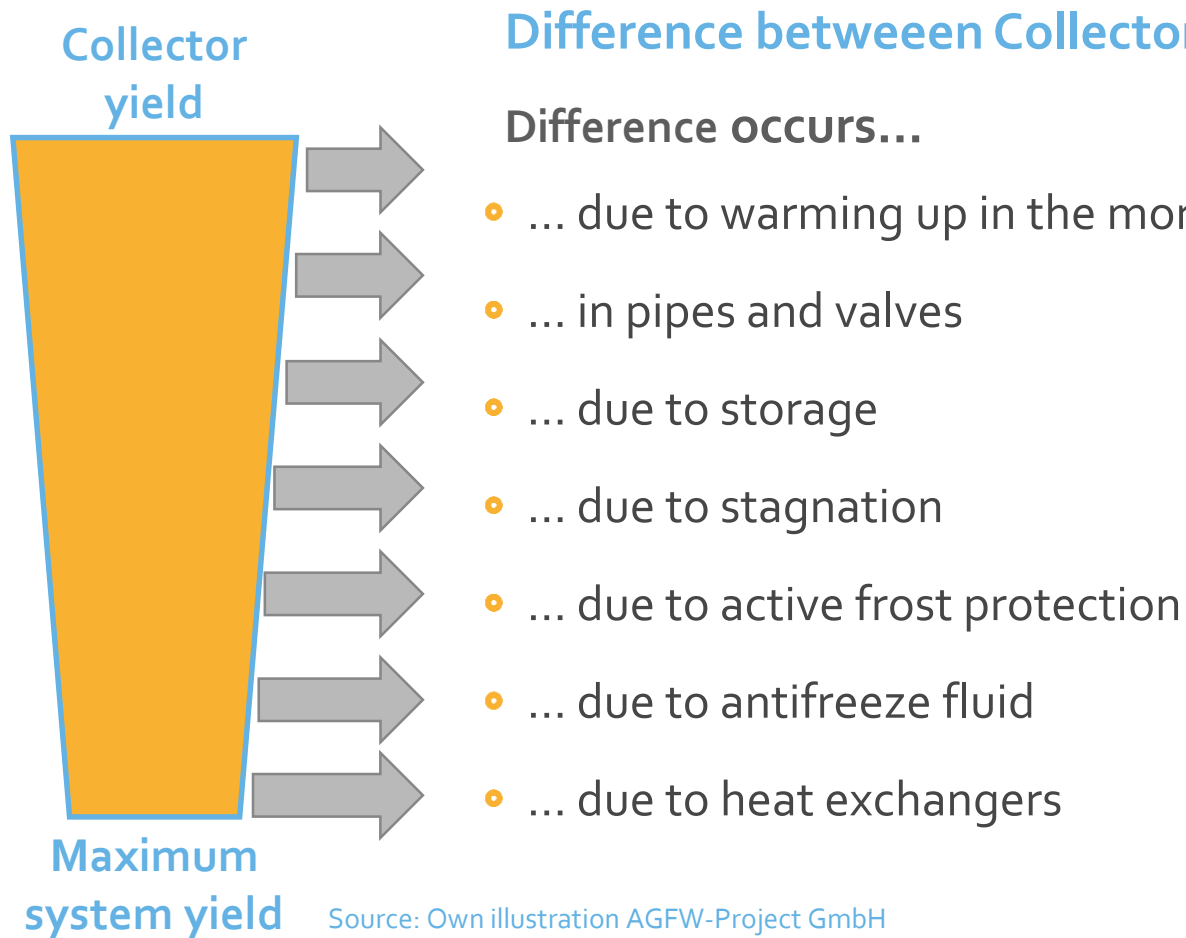

- Pressure increase and steam formation in the collector
- Steam development in the solar circuit
- High stress on the system components (e.g. pump gaskets)
- Possible cracking of glycol in the heat transfer fluid

Handling stagnation:

- Drainage of the solar fluid (especially necessary for glycol medium before stagnation state)
- Disable pumps & overpressure management
- Active cooling e.g. with groundwater and a second heat exchanger (extra well and absorption well will be needed)

→ Accepting stagnation as operation mode needs to be considered and planned within the planning and implementation phase

Technical & economic efficiency

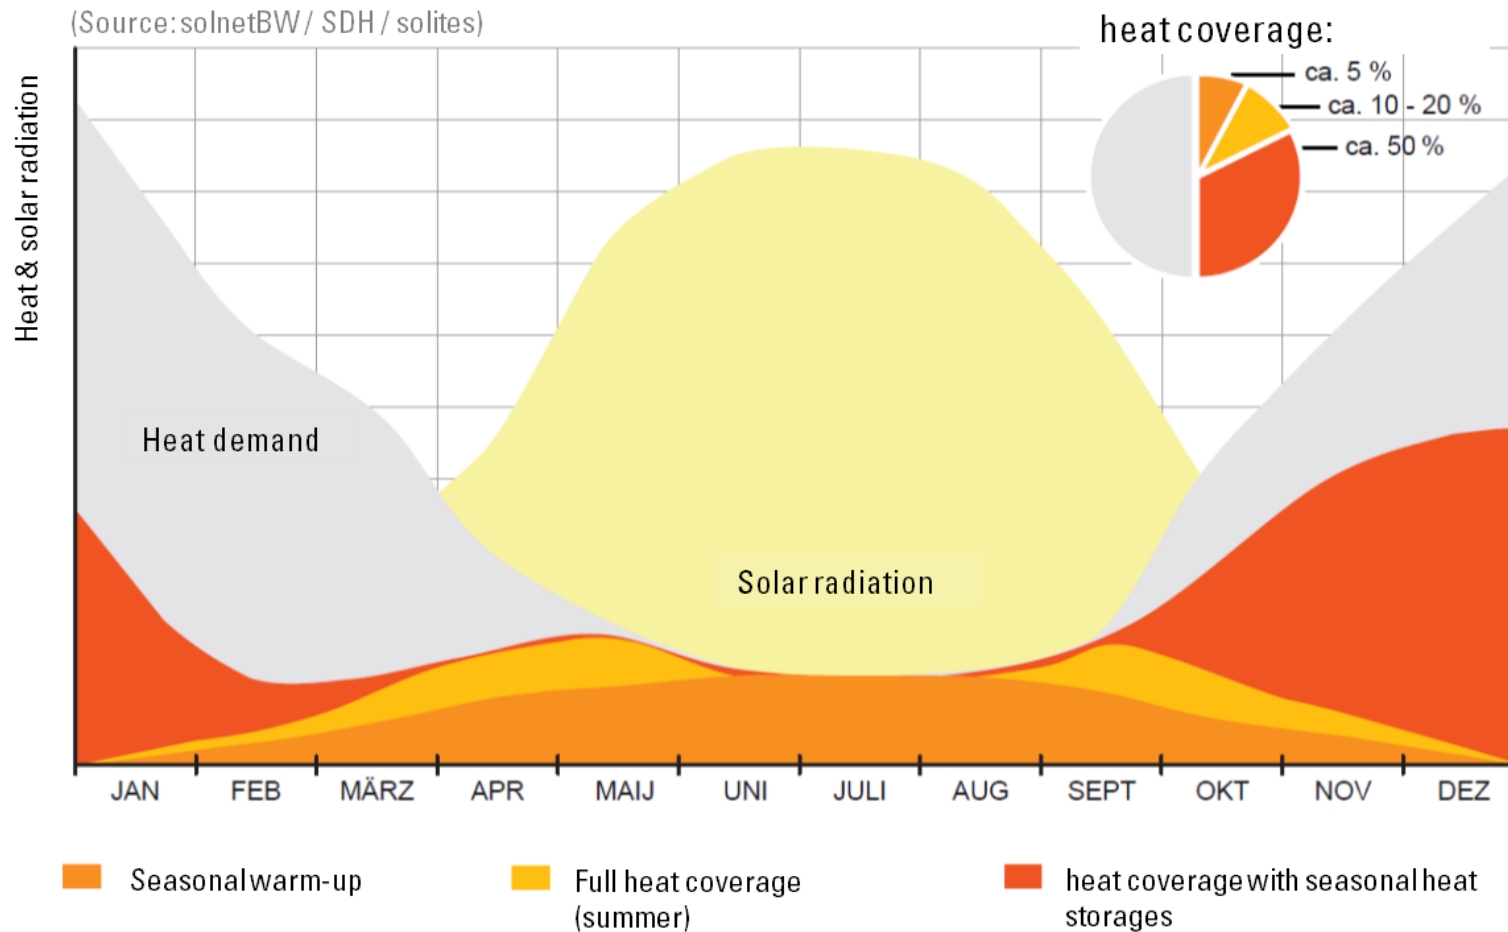

The difference between collector yield and maximum system yield can be roughly estimated by taking 10 % of the annual radiation

Annual cover ratio

Cover ration depends on:

- Integration of solar heat production in DH-systems (feed-in point: flow line / return flow)
- Planned heat utilization and operating temperature level
(Domestic hot water preparation, space heating, floor heating, etc.)
- Building structure (development area, existing building structure)
- Structure of the solar system (buffer storage, seasonal storage or direct integration)
- Direct or indirect feed-in
 - **No determined reference values!** (cover ratio needs to be estimated for each specific project)
 - SDH-plant can approx. reach between 30-60 % of the annual demand of domestic hot water preparation (complete coverage in summer)
 - Seasonal storage can increase the annual solar cover ratio by boosting stored water e.g. with a heat pump in transition periods

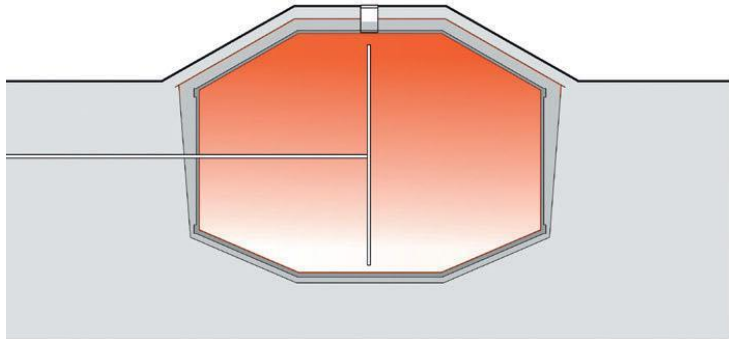

Increasing annual solar coverage through storages

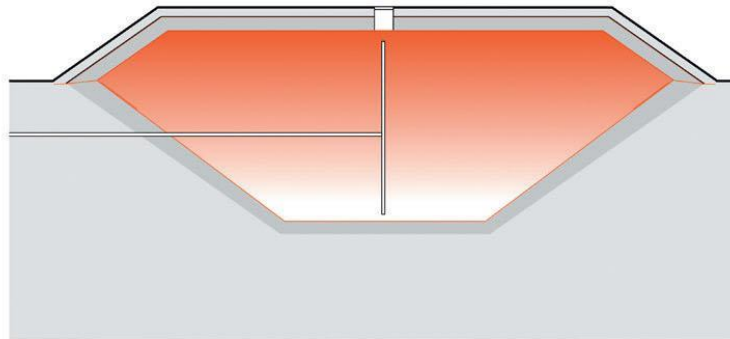

Source: Mathilde Kolbe [12]

Increasing annual solar coverage through storages

Heat storage (tank)
(60 to 80 kWh/m³)

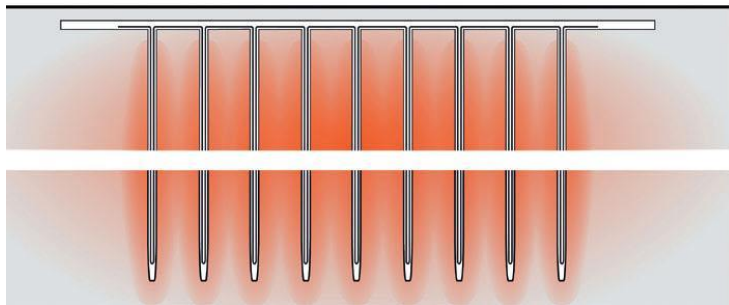

Pit store
(30 to 80 kWh/m³)

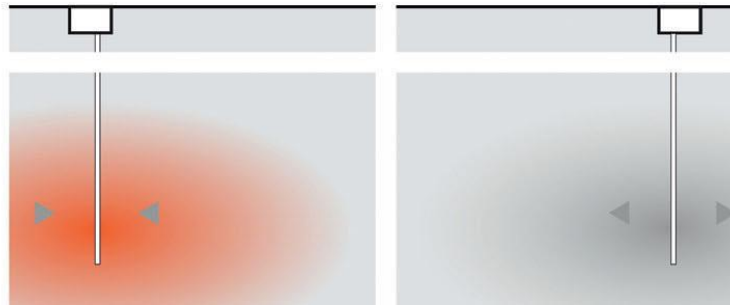

Storages options:

- Buffer storages (daywise storage)
- Seasonal storages (on the left)

Pie store (geothermal probe)
(15 to 30 kWh/m³)

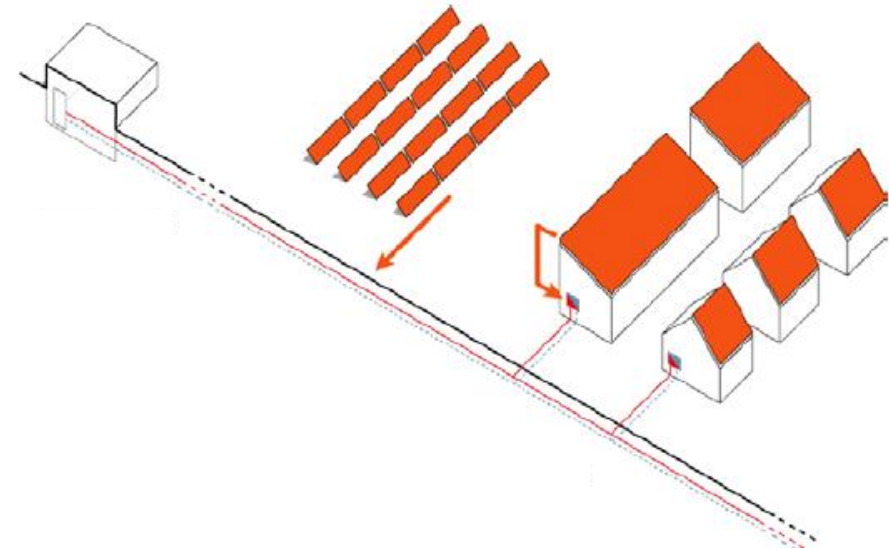

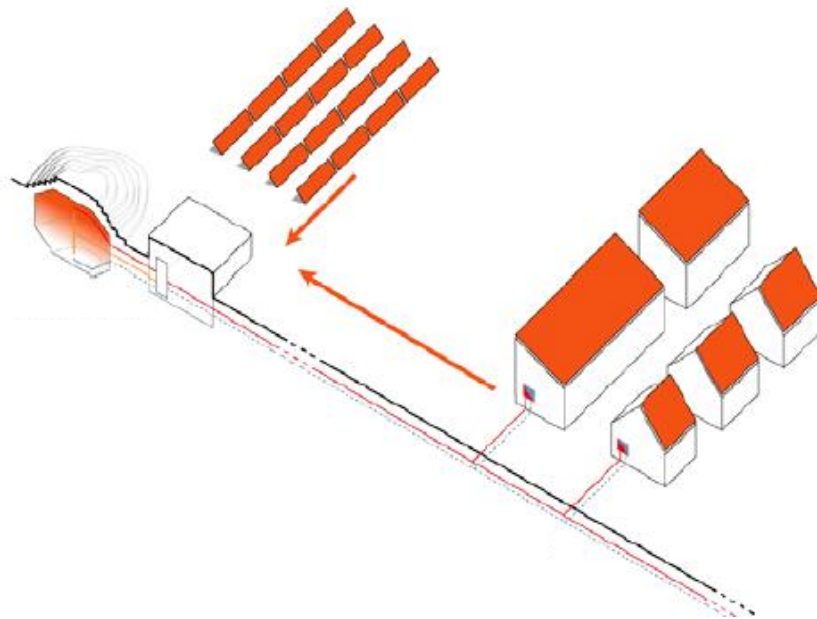

Aquifer storage
(30 to 40 kWh/m³)

Source: ikz.de (translated) [13]

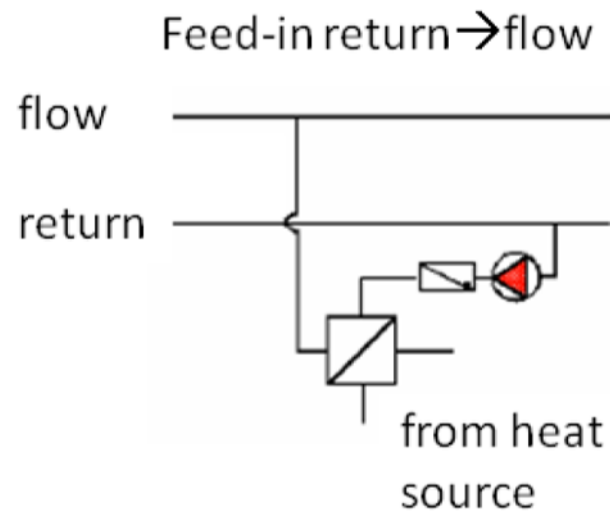

Feed-in principles – decentral / central

- „Decentral“: solar thermal plant is not close located to another major heat generator
- Central: feed-in point can be a transfer station (Solarthermal plant is located next to another heat generator e.g. heat plant / cogeneration unit)

Source: Solites (translated) [14]

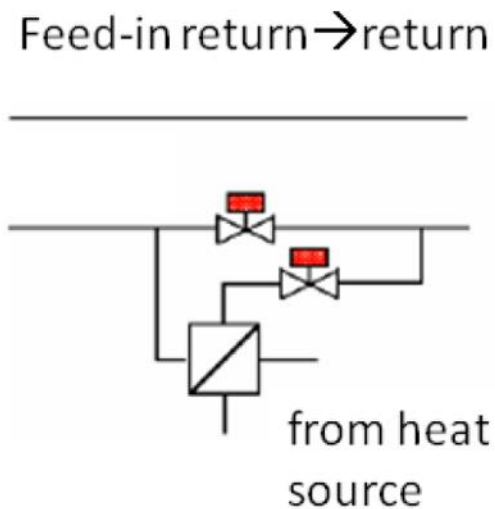

Feed-in principles – decentral

- Required temperature hub in the heat generator is defined by flow and return line of the heating grid
- Solar plant has to be operated at matched flow volumes, adjusted to the required flow temperature
- Feed-in pump has to overcome pressure differences between return and flow (could come to several bar)
 - + no change in return temperatures
 - high pump capacities needed

(Figure & Quoted from Solar District Heating (SDH) (2012) [15].

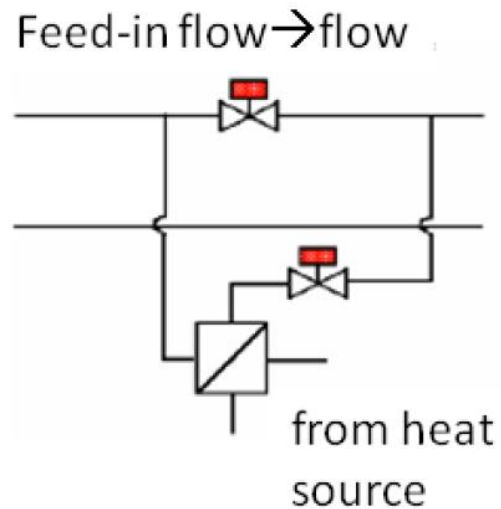

Feed-in principles – decentral

- Operating temperatures of solar plant lowest compared to other feed-in modes
- High solar yields can be expected
- No pumping energy required
- Constant mass flow in collectors
- Grid operators need to install a flow resistance to control feed-in by solar plant
- High return temperatures are not favourable

(Figure & Quoted from Solar District Heating (SDH) (2012). [18])

Feed-in principles – decentral

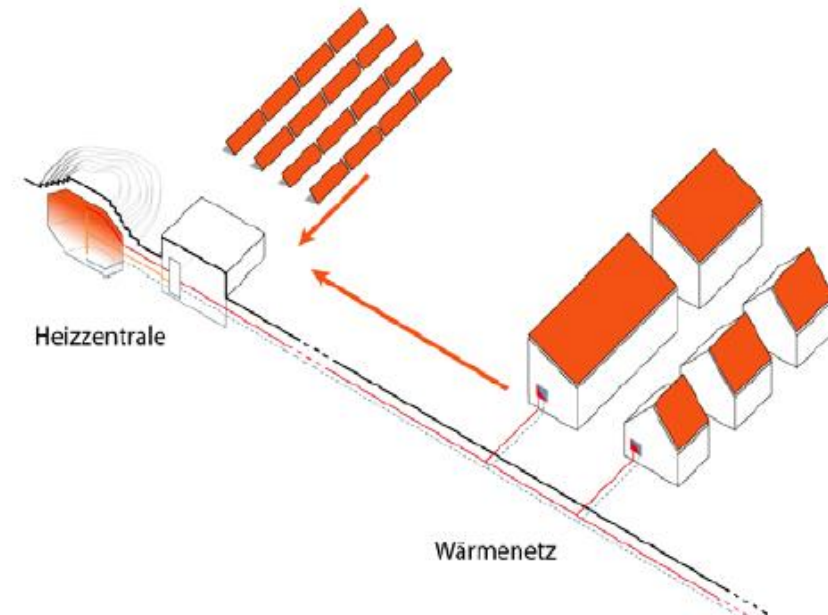

- High collector operating temperatures needed
- Low solar thermal efficiency and yields due to high temperature level

(Figure & Quoted from Solar District Heating (SDH) (2012). [18])

Feed-in principles – central

- Heat transfer takes place with heat exchangers at the central heating station
- clear distinction between solar cycle and DH-systems
- Feasible combination of solarthermal plant with other heat generating technologies possible

Source: Solites (translated) see [17]

SDH combined with other heat generating technologies

- Technically solar heat can be combined with any other energy source
- **The economical and environmental feasibility relies on multiple factors and needs to be estimated for each case!**

Few examples:

- **Increase of Return-flow**
 - Saving primary energy: increase of return flow temperature / coverage of domestic hot water preparation in summer)
 - High return flow temperatures not always wanted by grid operators
- **In combination with a cogeneration plant**
 - Solar thermal plants could lower output for electricity production

Key points regarding investment & operating costs

- Cost of land
- Collectors
- Collector field installation including piping in the field
- Anti-freeze fluid
- Transmission piping (collector field to heat exchanger unit)
- Heat exchanger (HX) unit (including pumps, expansion vessels, control, etc.)
- Connection to existing DH-systems
- Storage
- Control system
- Design & optimization
- Miscellaneous (e.g. building, ground shaping, fence, plant management etc.)

(Quoted from Solar District Heating (SDH) (2012). [16])

Key points regarding investment costs & economic efficiency

- Heat demand & dimension of the plant
- Storage size / seasonal storage needed (if, which other heat source e.g. heat pump will be needed?)
- Required landsize & price need to be evaluated with legal issues and construction law
- Which solar thermal system is needed? / Which temperature level is necessary?
- What are the existing structures of heat generation? What will be the future solar feed-in scenario?
 - piping expenses
- How much should be the estimated solar thermal heat coverage / annual duration?
 - Flow pipe / return pipe feed-in or both?
- What are the energy savings by other integrated/existing heat sources (e.g. (bio)gas / biomass etc.)?
- How much funding is possible?
- What are the financing costs (term, interest rate)?
- Development of energy costs within the next few years?

ANNEX I: Possible Scenario: Requirements for DH-supplier / Solar power plant operator

- Solar-DH is a volatile energy production
- Check at the feeding point, if the intended thermal load can be fed into the DH-network
- **Scenario:** loading condition “summer” - least thermal load, but the highest solar heat supply
- **Following principles are important to be considered:**
 - **Solar thermal load in the course of the day $<<$ thermal grid load summer**
→ heat absorption possible at any time as flow into the grid stays low
 - **Solar thermal load in the course of the day $<$ or $=$ thermal grid load summer**
→ heat absorption temporarily not possible → buffer storage might be useful
 - **Solar thermal load in the course of the day $>$ thermal grid load summer**
→ buffer storage necessary for feeding in the solar heat load with a time lag (if appropriate on demand)
- Plant size is depending on the maximum transportable heat

LowTEMP

SDH ONLINE-CALCULATOR

SDH
solar district heating

 

Welcome to the Online-Calculator for solar district heating (SDH) systems

This public domain online calculator for solar district heating (SDH) systems is available for interested market actors as an easy accessible and user friendly calculation program for a first dimensioning and forecast of performance and economical values for solar district heating systems.

The calculator was developed based on numerous and detailed dynamic system simulations with the simulation program TRNSYS and under consideration of a large number of influencing factors. Calculations are possible for the distributed and centralised system concepts listed in the selection box.
